Washington Health System is pleased to announce a cutting-edge cancer therapy now being offered to patients at Washington Health System.

Radioembolization is a technique where small radioactive particles are infused through catheters inserted into arteries that supply blood flow to primary or metastatic lesions in the liver. This has been shown to be a safe and effective treatment with palliative and life-extending results. While this treatment is traditionally offered at large academic and tertiary referral centers nationally, few community centers have the clinical expertise to offer this therapy. With a strong clinical Interventional Radiology practice partnered with Nuclear Medicine and Radiation Physics, our patients can have the convenience of receiving this advanced treatment locally.

With the addition of radioembolization, the Interventional Radiology Department at Washington Health System now offers the full spectrum of advanced cancer therapies in the field of Interventional Oncology. These techniques include Chemoembolization and Percutaneous Ablation for treatment of primary and metastatic liver cancer, renal cell carcinoma, and primary and metastatic lung cancer among others.
